# Dynamic memory

Deallocation

- Variables are pieces of information stored in a computers memory.
- Don't typically care where in the memory.
- Just care that we can use the variables.
- Pointers store memory locations.
  - Find where variables are stored.
  - Move through memory.
- In Python almost everything is a pointer.
  - So we don't notice.
  - Technically Python uses aliases not a pointers.
- In C++ pointers are explicitly stated.

References

Dynamic memory

Deallocation

- Variables are stored in memory.
  - Can be visualised as series of uniquely addressed boxes.

Address	Value
1242	'Q'

- OS picks an unused memory location e.g. 1242
  - This location must have enough space to store the variable.
  - Different variable types have different sizes.
  - I.e. sizeof(int) == 4 bytes, sizeof(double) == 8 bytes.
    - Need multiple 'boxes'.
- myVariable is our name for memory location 1242.
- In Python can get memory location info using id(myVariable) function.

Dynamic memory Allocation

Deallocation

Recap

Variables are named blocks of memory.

- Pointers are variables that hold memory addresses.
- Each type of variable has an associated pointer type.
- We declare a pointer using an \* after the type name.

```
typename * variableName;
int * i;
char * c;
float * f;
```

Pointers "point to" other variables in memory.

# Dynamic memory Allocation

Deallocatio

Recap

Pointers don't have to point anywhere.

- If they don't point to anything they are called null pointers.
- Dereferencing a null pointer will cause your program to crash.
- You can set any pointer to point to null.
- Old way (still works).

```
int *myPointer = NULL;
```

New C++11 way (use this one).

```
int *myPointer = nullptr;
```

# Why use pointers/references?

#### Pointers

Referencing
Dereferencing
Arithmetic
Nulls

### Why do we care?

Danger Required for Python/C++ differences

#### References

Dynamic memory

Deallocatio

Recap

### Advantages.

- Pointers/references are small.
  - Instead of copying big data structures around just copy the pointer.
  - E.g. an array storing a picture == millions of bytes.
  - Pointer/reference to an array storing a picture == 4-8 bytes.
- Pointers are required for dynamic memory allocation (C++).
  - Required for some behaviours.

### Disadvantages.

- Pointers are dangerous.
  - Buggy pointer code can crash your program/computer.

- In Python we passed a mutable type to the function.
  - Actually just sends an 'alias' of the original mutable structure.
  - Mutable types, e.g. lists, sets, dicts etc.
  - Changing value/s in function changes original variable/s too.
  - Aliases are similar to pointers/references.

Deallocation

Recap

The C++ program didn't work, why?

- In Python we passed a mutable type to the function.
  - Actually just sends an 'alias' of the original mutable structure.
  - Mutable types, e.g. lists, sets, dicts etc.
  - Changing value/s in function changes original variable/s too.
  - Aliases are similar to pointers/references.
- If we passed an immutable type Python would create actual copy and send that instead.
  - Immutable types, e.g. int, float, string.
  - Original would stay same regardless.

Recap

### The C++ program didn't work, why?

- In Python we passed a mutable type to the function.
  - Actually just sends an 'alias' of the original mutable structure.
  - Mutable types, e.g. lists, sets, dicts etc.
  - Changing value/s in function changes original variable/s too.
  - Aliases are similar to pointers/references.
- If we passed an immutable type Python would create actual copy and send that instead.
  - Immutable types, e.g. int, float, string.
  - Original would stay same regardless.
- When C++ variable passed to a function, always creates a new variable.
  - New variable stored in a new memory location.
  - Even for vectors, arrays etc.
- Changing value/s in function doesn't change original variable/s.
- How to fix?

Recap

C++ also has references.

- Safer than pointers.
  - Less powerful.
- Declared like pointers but with & instead of \*.

```
int myVariable = 42;
int &refA = myVariable;
int &refB = refA;
```

Recap

Looking at the earlier function example.

```
int some_function( array<int,5> &values )
{
  for( int i=0; i<values.size(); ++i )</pre>
    values[i] *= 2;
int main()
  array<int,5> v {0, 1, 2, 3, 4};
  some_function(v);
  for( int i : v ) // 0,2,4,6,8
    cout << i << ",";
  cout << endl;</pre>
  return 0;
```

### Why do we care?

Danger Required for Python/C++ differences

#### References

# Dynamic memory

Deallocation

Recap

Most important feature of pointers.

- Can't always know how much memory program will need at compile time.
  - E.g. a program that reads in a file, memory required depends on size of the file.
- Have to allocate it at run time.
  - Dynamic memory allocation.
  - As opposed to Static memory allocation.
- Code gives itself more memory, has to remember to give it back when it's finished
  - Deallocation.

Dynamic memory Allocation

Deallocation

Recap

Used to have to dynamically ask for more memory.

- Create a chunk of memory of the size requested.
- Return a pointer to it so know where it is.

E.g. vectors.

- C/C++ arrays can't be resized.
- But vectors are resizeable arrays.
  - How?
  - Dynamically allocate new array.
  - Copy old array contents into new array.
  - 3 Deallocate old array.

Allocation

Recap

How to dynamically allocate arrays?

- Have to use old, C-style arrays.
  - For the moment, talk again after C++17.

```
int staticArray[10]; // works
int* dynamicArray = new int[10]; // works
```

```
int size;
cout << "How big an array do you want?" << endl;
cin >> size;
int staticArray[size]; // won't compile
int* dynamicArray = new int[size]; // works
```

Dynamic memory

Allocation

Recap

Deallocation

C++ does not have automatic garbage collection.

- C++11 comes close.
- New features shared\_ptr and unique\_ptr, weak\_ptr.
- Special new smart pointers.
  - Automatically deallocate memory when nothing pointing at it.
  - Don't need to remember to delete.
  - No memory leaks!
- shared\_ptr is 99% the same as 'normal' pointers.
  - unique\_ptr and weak\_ptr have extra features.

Deallocation

### STRONGLY recommend you use shared\_ptr.

- Whenever dynamically allocating memory.
- No memory leaks.

```
int main()
    shared_ptr<int> pointerA = make_shared<int>();
    *pointerA = 42;
    cout << pointerA.use_count() << endl; // 1</pre>
    shared_ptr<int> pointerB = pointerA;
    cout << pointerA.use_count() << endl; // 2</pre>
    pointerB = nullptr;
    cout << pointerA.use_count() << endl; // 1</pre>
    return 0;
```
